

Machine Learning Assignment 2

Bohan YANG, 2330016056

October 21, 2025

Question 1

Let $\mathcal{D} = \{X_1, \dots, X_n\}$ be i.i.d. samples from a Poisson distribution with rate parameter λ , i.e. $X_i \sim \text{Poisson}(\lambda)$.

Denote $S = \sum_{i=1}^n X_i$ and $\bar{X} = \frac{1}{n} \sum_{i=1}^n X_i$.

(a)

The likelihood function is

$$L(\lambda) = \prod_{i=1}^n P(X_i | \lambda) = \prod_{i=1}^n \frac{\lambda^{X_i} e^{-\lambda}}{X_i!} = \frac{\lambda^S e^{-n\lambda}}{\prod_{i=1}^n X_i!}.$$

The log-likelihood is

$$\ell(\lambda) = S \log \lambda - n\lambda - \sum_{i=1}^n \log(X_i!).$$

Taking the derivative w.r.t. λ and setting it to zero gives

$$\frac{d\ell}{d\lambda} = \frac{S}{\lambda} - n = 0 \implies \hat{\lambda}_{\text{MLE}} = \frac{S}{n} = \bar{X}.$$

Because $\mathbb{E}[X_i] = \lambda$, the estimator is unbiased:

$$\mathbb{E}[\hat{\lambda}_{\text{MLE}}] = \mathbb{E}[\bar{X}] = \frac{1}{n} \sum_{i=1}^n \mathbb{E}[X_i] = \lambda.$$

(b)

Assume the prior $\lambda \sim \text{Gamma}(\alpha, \beta)$ (rate parameterization) with pdf

$$p(\lambda | \alpha, \beta) = \frac{\beta^\alpha}{\Gamma(\alpha)} \lambda^{\alpha-1} e^{-\beta\lambda}, \quad \alpha > 0, \beta > 0.$$

The posterior is proportional to the product of the prior and the likelihood:

$$p(\lambda \mid \mathcal{D}) \propto p(\lambda)L(\lambda) \propto \lambda^{\alpha-1}e^{-\beta\lambda} \lambda^S e^{-n\lambda} = \lambda^{(\alpha+S)-1}e^{-(\beta+n)\lambda}.$$

Hence,

$$\lambda \mid \mathcal{D} \sim \text{Gamma}(\alpha + S, \beta + n).$$

(c)

From part (b), we know

$$\lambda \mid \mathcal{D} \sim \text{Gamma}(\alpha', \beta'), \quad \text{where } \alpha' = \alpha + S, \beta' = \beta + n.$$

$$p(\lambda \mid \alpha', \beta') = \frac{(\beta')^{\alpha'}}{\Gamma(\alpha')} \lambda^{\alpha'-1} e^{-\beta'\lambda}, \quad \lambda > 0.$$

To find the mode (i.e., the most probable value of λ), we maximize $p(\lambda \mid \alpha', \beta')$ with respect to λ .

$$\begin{aligned} \ell(\lambda) &= \log p(\lambda \mid \alpha', \beta') = (\alpha' - 1) \log \lambda - \beta' \lambda + \text{constant}. \\ \frac{d\ell}{d\lambda} &= \frac{\alpha' - 1}{\lambda} - \beta'. \end{aligned}$$

Setting the derivative to zero gives

$$\frac{\alpha' - 1}{\lambda} - \beta' = 0 \implies \lambda_{\text{mode}} = \frac{\alpha' - 1}{\beta'}.$$

This stationary point is only valid if $\alpha' > 1$; otherwise, the pdf is monotonically decreasing and the mode occurs at the boundary $\lambda = 0$.

Therefore, the mode of the posterior distribution (which is the MAP estimator) is

$$\hat{\lambda}_{\text{MAP}} = \begin{cases} \frac{\alpha' - 1}{\beta'}, & \alpha' > 1, \\ 0, & \alpha' \leq 1. \end{cases}$$

Since $\alpha' = \alpha + S$ and $\beta' = \beta + n$, we obtain

$$\hat{\lambda}_{\text{MAP}} = \begin{cases} \frac{\alpha + S - 1}{\beta + n}, & \alpha + S > 1, \\ 0, & \alpha + S \leq 1. \end{cases}$$

Equivalently, using the sample mean $\bar{X} = \frac{S}{n}$,

$$\hat{\lambda}_{\text{MAP}} = \frac{n\bar{X} + \alpha - 1}{\beta + n} \quad (\alpha + S > 1).$$

Question 2

$$y_i \sim \mathcal{N}(\mu, 1), \quad i = 1, 2, \dots, n.$$

(a)

Since the estimator is constant,

$$\mathbb{E}[\hat{\mu}] = 1.$$

Hence,

$$\text{Bias}(\hat{\mu}) = \mathbb{E}[\hat{\mu}] - \mu = 1 - \mu, \quad \text{Var}(\hat{\mu}) = 0.$$

Therefore, the mean squared error (MSE) is

$$\text{MSE} = (1 - \mu)^2.$$

Interpretation: This estimator ignores the data and is generally not good, except in the special case where the true mean $\mu = 1$.

(b)

Since $y_1 \sim \mathcal{N}(\mu, 1)$,

$$\mathbb{E}[\hat{\mu}] = \mu, \quad \text{Var}(\hat{\mu}) = 1.$$

Thus,

$$\text{Bias}(\hat{\mu}) = 0, \quad \text{MSE} = 1.$$

Interpretation: This estimator is unbiased but has high variance, because it uses only one observation instead of all n samples.

(c)

The estimator is defined as

$$\hat{\mu} = \arg \min_{\mu} \sum_{i=1}^n (y_i - \mu)^2 + \lambda \mu^2, \quad \lambda > 0.$$

Taking the derivative and setting it to zero:

$$-2 \sum_{i=1}^n (y_i - \mu) + 2\lambda\mu = 0 \quad \Rightarrow \quad (n + \lambda)\hat{\mu} = \sum_{i=1}^n y_i.$$

Hence,

$$\boxed{\hat{\mu} = \frac{n}{n + \lambda} \bar{y}}, \quad \bar{y} = \frac{1}{n} \sum_{i=1}^n y_i.$$

Expectation:

$$\mathbb{E}[\hat{\mu}] = \frac{n}{n + \lambda} \mathbb{E}[\bar{y}] = \frac{n}{n + \lambda} \mu.$$

Bias:

$$\text{Bias}(\hat{\mu}) = \mathbb{E}[\hat{\mu}] - \mu = \left(\frac{n}{n+\lambda} - 1 \right) \mu = -\frac{\lambda}{n+\lambda} \mu.$$

Variance: Since $\text{Var}(\bar{y}) = \frac{1}{n}$,

$$\text{Var}(\hat{\mu}) = \left(\frac{n}{n+\lambda} \right)^2 \text{Var}(\bar{y}) = \left(\frac{n}{n+\lambda} \right)^2 \frac{1}{n} = \frac{n}{(n+\lambda)^2}.$$

MSE:

$$\text{MSE}(\hat{\mu}) = \text{Bias}^2 + \text{Var} = \frac{\lambda^2 \mu^2 + n}{(n+\lambda)^2}.$$

Interpretation: This estimator is biased toward 0, but its variance is smaller than that of the unbiased sample mean. It can achieve a lower mean squared error (MSE) when n is small or when we expect μ to be close to 0.

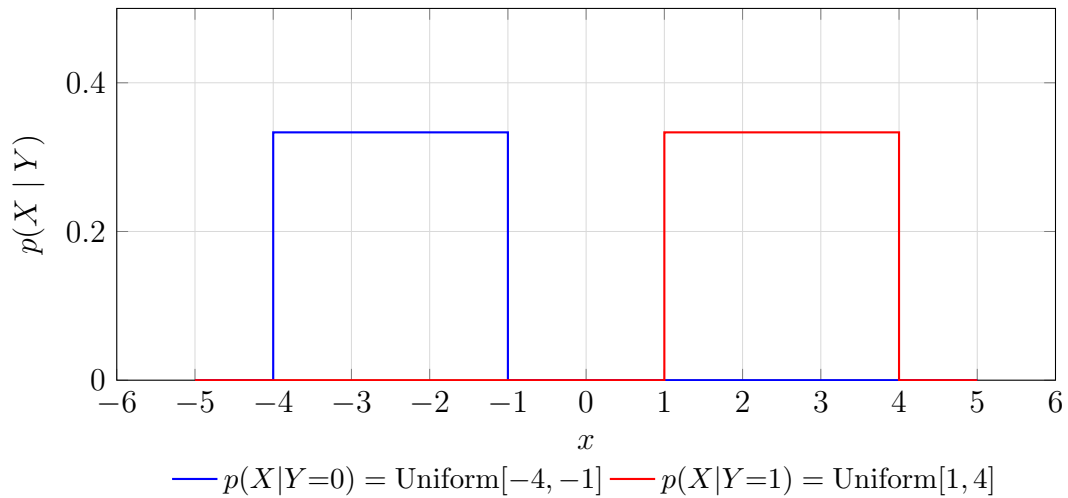

Question 3

(a)

$$p(X \mid Y = 1) = \text{Uniform}[1, 4], \quad p(X \mid Y = 0) = \text{Uniform}[-4, -1].$$

Thus,

$$p(X \mid Y = 1) = \begin{cases} \frac{1}{3}, & 1 \leq X \leq 4, \\ 0, & \text{otherwise,} \end{cases} \quad p(X \mid Y = 0) = \begin{cases} \frac{1}{3}, & -4 \leq X \leq -1, \\ 0, & \text{otherwise.} \end{cases}$$

(b)

Since the two distributions have disjoint supports and equal priors

$$P(Y = 0) = P(Y = 1) = \frac{1}{2},$$

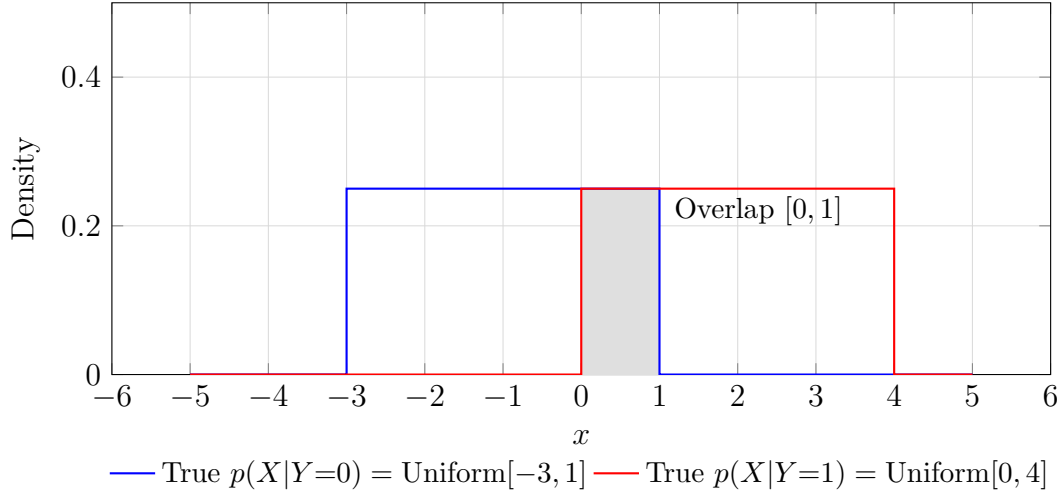

the Bayes classifier simply predicts the class whose support contains x . Therefore, the classifier makes no mistakes:

Bayes error = 0.

(c)

$$p(X | Y = 1) = \text{Uniform}[0, 4], \quad p(X | Y = 0) = \text{Uniform}[-3, 1].$$

$$\text{BayesErr} = \frac{1}{2} \int \min\{p(x | Y = 1), p(x | Y = 0)\} dx = \frac{1}{2} \times \frac{1}{4} \times 1 = \boxed{\frac{1}{8} = 0.125}.$$

(d)

For a uniform distribution $\text{Uniform}[a, b]$, we have:

$$\mu = \frac{a + b}{2}, \quad \sigma^2 = \frac{(b - a)^2}{12}.$$

Hence,

$$p(X | Y = 0) \approx \mathcal{N}(-2.5, 0.75), \quad p(X | Y = 1) \approx \mathcal{N}(2.5, 0.75).$$

With equal priors and identical variances, the decision boundary occurs at:

$$x^* = \frac{\mu_0 + \mu_1}{2} = 0.$$

Therefore, the classifier predicts $Y = 1$ if $x > 0$, and $Y = 0$ otherwise.

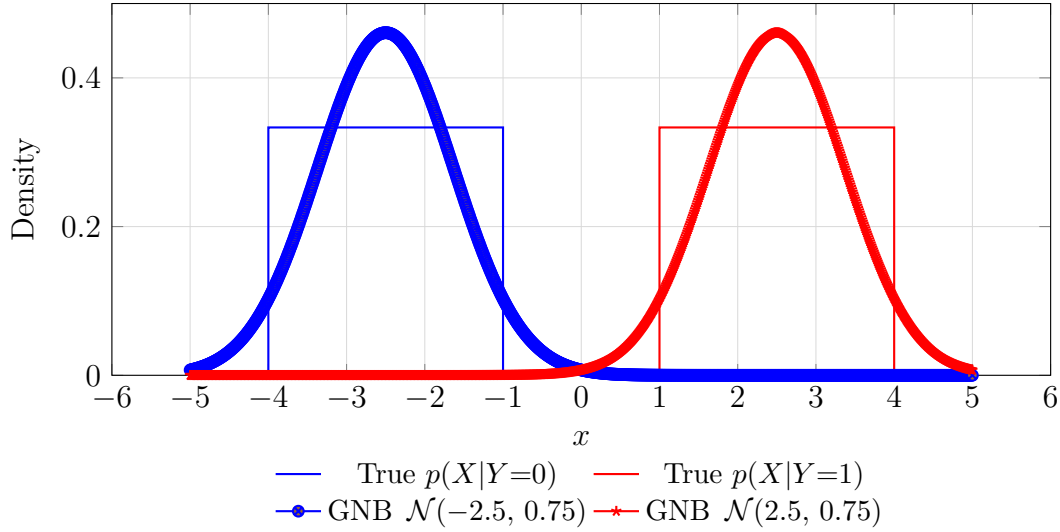

The classification error of GNB is:

$$\text{Err}_{\text{GNB}} = \frac{1}{2} \int_{-4}^{-1} \mathbf{1}\{x > x^*\} \frac{1}{3} dx + \frac{1}{2} \int_1^4 \mathbf{1}\{x < x^*\} \frac{1}{3} dx.$$

Since the threshold $x^* = 0$ lies between the two non-overlapping intervals, both integrals are zero and thus:

$$\boxed{\text{Err}_{\text{GNB}} = 0.}$$

Although the GNB model is biased (it cannot represent the true uniform shape), the symmetry of the problem yields zero misclassification error.

(e)

With a finite n , the estimated class means and variances, $\hat{\mu}_k, \hat{\sigma}_k^2$, fluctuate due to sampling noise.

Consequently, the GNB decision rule (and its threshold) fluctuates as well.

This introduces a variance component of error on top of the (model) *bias*.

Question 4

Let $Y \in \{0, 1\}$ with prior $\pi = P(Y = 1)$, and $\mathbf{X} = (X_1, \dots, X_n)$ with conditional independence given Y (naïve Bayes). For each feature i and class $k \in \{0, 1\}$, assume a univariate Gaussian:

$$P(X_i | Y = k) = \mathcal{N}(\mu_{i,k}, \sigma_{i,k}^2), \quad i = 1, \dots, n.$$

Hence

$$p(\mathbf{x} | Y = k) = \prod_{i=1}^n \frac{1}{\sqrt{2\pi} \sigma_{i,k}} \exp\left(-\frac{(x_i - \mu_{i,k})^2}{2\sigma_{i,k}^2}\right).$$

By Bayes' rule,

$$P(Y = 1 | \mathbf{x}) = \frac{\pi p(\mathbf{x} | Y = 1)}{\pi p(\mathbf{x} | Y = 1) + (1 - \pi) p(\mathbf{x} | Y = 0)}.$$

log-odds:

$$\Lambda(\mathbf{x}) := \log \frac{P(Y = 1 | \mathbf{x})}{P(Y = 0 | \mathbf{x})} = \log \frac{\pi}{1 - \pi} + \log \frac{p(\mathbf{x} | Y = 1)}{p(\mathbf{x} | Y = 0)}.$$

(a) $\sigma_{i,0} = \sigma_{i,1} = \sigma_i$

Under the special assumption used in class/readings, each feature has a class-independent standard deviation $\sigma_i > 0$. Then

$$\log \frac{p(\mathbf{x} | Y = 1)}{p(\mathbf{x} | Y = 0)} = \sum_{i=1}^n \left[-\frac{(x_i - \mu_{i,1})^2}{2\sigma_i^2} + \frac{(x_i - \mu_{i,0})^2}{2\sigma_i^2} \right] = \sum_{i=1}^n \frac{1}{2\sigma_i^2} \left((x_i^2 - 2x_i\mu_{i,1} + \mu_{i,1}^2) - (x_i^2 - 2x_i\mu_{i,0} + \mu_{i,0}^2) \right).$$

The x_i^2 terms cancel:

$$\log \frac{p(\mathbf{x} | Y = 1)}{p(\mathbf{x} | Y = 0)} = \sum_{i=1}^n \left(\frac{\mu_{i,1} - \mu_{i,0}}{\sigma_i^2} \right) x_i + \frac{1}{2} \sum_{i=1}^n \frac{\mu_{i,0}^2 - \mu_{i,1}^2}{\sigma_i^2}.$$

Therefore the log-odds is linear in \mathbf{x} :

$$\Lambda(\mathbf{x}) = w_0 + \sum_{i=1}^n w_i x_i, \quad \text{with} \quad w_i = \frac{\mu_{i,1} - \mu_{i,0}}{\sigma_i^2}, \quad w_0 = \log \frac{\pi}{1 - \pi} + \frac{1}{2} \sum_{i=1}^n \frac{\mu_{i,0}^2 - \mu_{i,1}^2}{\sigma_i^2}.$$

Applying the logistic link,

$$P(Y = 1 | \mathbf{x}) = \frac{1}{1 + \exp(-\Lambda(\mathbf{x}))} = \sigma \left(w_0 + \sum_{i=1}^n w_i x_i \right),$$

which is *exactly* the functional form of logistic regression.

(b) $\sigma_{i,0} \neq \sigma_{i,1}$

$$\begin{aligned} \log \frac{p(\mathbf{x} | Y = 1)}{p(\mathbf{x} | Y = 0)} &= \sum_{i=1}^n \left[\log \frac{\sigma_{i,0}}{\sigma_{i,1}} - \frac{(x_i - \mu_{i,1})^2}{2\sigma_{i,1}^2} + \frac{(x_i - \mu_{i,0})^2}{2\sigma_{i,0}^2} \right]. \\ -\frac{(x_i - \mu_{i,1})^2}{2\sigma_{i,1}^2} + \frac{(x_i - \mu_{i,0})^2}{2\sigma_{i,0}^2} &= \underbrace{\left(\frac{1}{2\sigma_{i,0}^2} - \frac{1}{2\sigma_{i,1}^2} \right)}_{\text{quadratic coeff.}} x_i^2 + \underbrace{\left(\frac{\mu_{i,1}}{\sigma_{i,1}^2} - \frac{\mu_{i,0}}{\sigma_{i,0}^2} \right)}_{\text{linear coeff.}} x_i + \underbrace{\left(\frac{\mu_{i,0}^2}{2\sigma_{i,0}^2} - \frac{\mu_{i,1}^2}{2\sigma_{i,1}^2} \right)}_{\text{constant}}. \\ \Lambda(\mathbf{x}) &= \log \frac{\pi}{1 - \pi} + \sum_{i=1}^n \log \frac{\sigma_{i,0}}{\sigma_{i,1}} + \sum_{i=1}^n \left(\frac{1}{2\sigma_{i,0}^2} - \frac{1}{2\sigma_{i,1}^2} \right) x_i^2 + \sum_{i=1}^n \left(\frac{\mu_{i,1}}{\sigma_{i,1}^2} - \frac{\mu_{i,0}}{\sigma_{i,0}^2} \right) x_i + \sum_{i=1}^n \left(\frac{\mu_{i,0}^2}{2\sigma_{i,0}^2} - \frac{\mu_{i,1}^2}{2\sigma_{i,1}^2} \right). \end{aligned}$$

(c) conclusion

unless $\sigma_{i,0} = \sigma_{i,1}$ for every i , the coefficients of x_i^2 do not cancel, so the log-odds is *quadratic* in \mathbf{x} .

Hence the form is not the logistic regression form.
